REC'D 22 APR 2004

WIPD

PST

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

I also certify that the attached copy of the request for grant of a Patent (Form 1/77) bears an amendment, effected by this office, following a request by the applicant and agreed to by the Comptroller-General.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Request for grant of a patent

(See the notes on the back of this form. You can also get an explanatory leaflet, from the Patent Office to help you fill in this form)

1.	Your reference	ADT0171 (P7195)		
2.	Patent application number (The Patent Office will fill in this part)	0306678.4		
3.	Full name, address and postcode of the or of each applicant (underline all surnames)	QINETIQ LIMITED 85 Buckingham Gate, London, SW1 6PD.		
	Patents ADP number (if you know it)			
	If the applicant is a corporate body, give the country/state of its incorporation	GREAT BRITAIN 8/83857001		
4.	Title of the invention	IMAGING APPARATUS		
5.	Name of your agent (if you have one)	BARKER BRETTELL QINETIQ LIMITED 5/77 19/1/04		
	"Address for service" in the United Kingdom to which all correspondence should be sent (including the postcode)	138 HAGLEY ROAD EDGBASTON BIRMINGHAM B16 9PW		
	Patents ADP number (if you know it)	7442494002 ✓		
6.	If you are declaring priority from one or more earlier patent applications, give the country and the date of filing of the or of each of these earlier applications and (if you know it) the or each application number	Country	Priority application number (if you know it)	Date of Filing (day/month/year)
7.	If this application is divided or otherwise derived from an earlier UK application, give the number and the filing date of the earlier application	Number of earlier application		Date of filing (day/month/year)
8.	Is a statement of inventorship and of right to grant of a patent required in support of this request (Answer 'Yes' if: a) any applicant named in part 3 is not an inventor, or b) there is an inventor who is not named as an applicant, or c) any named applicant is a corporate body. See note (d))			
	YES

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- 1) If you need help to fill in this form or you have any questions, please contact the Patent Office on 01645 500505
 - 2) Write your answers in capital letters using black ink or you may type them.
 - 3) If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
 - 4) If you have answered 'Yes' *Patents Form 7/77* will need to be filed.
 - 5) Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

IMAGING APPARATUS

This invention relates to an imaging apparatus. More particularly, but not exclusively, it relates to a millimetre wave imaging apparatus.

5

A current real-time passive millimetre wave imager 100, as shown in Figure 1, typically employs a mechanical scanning device 102 located behind a receiver array 104 to scan a wide field of view onto a focussing reflector 106. The receiver array 104 typically lies in the focal plane of the focussing reflector 106. Increasing the number of elements in an imager's receiver array allows the dwell time on each pixel of an image to be increased during a mechanical scan, thereby increasing the signal to noise ratio for each pixel and increasing image quality. However, due to physical size constraints upon the size of receiver array elements, such an increase in the number of elements causes beam obscuration, due to the geometry of the imager 100.

Another problem associated with current imaging apparatus is that it samples the field of view at a sub-Nyquist rate, typically at less than half Nyquist rate. This is particularly true with staring arrays in which there is no mechanical scanning of the field of view across the focal plane. Sub-Nyquist sampling leads to poor image quality. This is why scanning arrays have hitherto provided better quality images than staring arrays.

25 According to the present invention there is provided a millimetre wave imaging apparatus comprising scanning means, focussing means and a plurality of receiver elements, the focussing means being physically interposed between the scanning means and the receiver elements, the scanning means being arranged to scan radiation from a field of view onto said focussing means such that focussed radiation from a region of the

30

field of view is incident upon at least one of the plurality of receiver elements.

5 This architecture allows a large number of elements to be introduced into the focal plane, without causing beam obscuration for a large field of view, as the receiver elements do not lie in the path of radiation passing from the scanning means to the focussing means. This enables higher sensitivities to be achieved than existing mechanical scanning passive millimetre wave imagers.

10

Additionally, this architecture allows Nyquist sampling and relative calibration to be achieved using a high-density receiver element array.

The scanning means may be two prisms. The prisms may be wedge prisms. The prisms may be of uniform thickness and varying refractive
15 index across their respective cross-sections. Each of the prisms may be arranged to rotate. The prisms may be arranged to rotate in opposite directions to each other. The prisms may be arranged to produce an elliptical scan path in the focal plane. The elliptical scan path may have a minor diameter that corresponds approximately to half the array spacing
20 of the elements in an array. This ensures that Nyquist sampling is achieved in the direction of the array. It also results in adjacent elements sampling the same region of a scene alternately, which allows relative calibration of elements to be employed.

25 The plurality of receiver elements may be arranged in a linear, or a curvilinear array. The prisms may be arranged to rotate at a rate of at least 25 revolutions per second.

The scanning means may be a prism. The prism may be a wedge prism.
30 The prisms may be of uniform thickness and varying refractive index across a cross-section thereof. The prism may be arranged to rotate. The

prism may be arranged to produce a circular scan path in the focal plane. The plurality of receiver elements may be arranged in a sparse two dimensional, or a linear array.

- 5 An imaging apparatus with a single prism scanning means is cheaper and simpler to manufacture than a dual prism apparatus; only a single prism and drive means need to be produced.

The focussing means may be a reflector lens. The reflector lens may
10 comprise a first polarising element, typically a wire grid. The reflector lens may further comprise a polarisation altering element, for example a Ferrite or a Faraday plate, typically arranged to alter the polarisation of radiation incident thereupon by about 45° . The reflector lens may also
15 comprise a second polarising element, typically a wire grid, usually arranged to reflect radiation transmitted by the first polarising element. Typically, the radiation incident upon the second polarising element is polarised at 45° to that transmitted by the first polarising element.

The scanning means, which may be arranged to define an entrance pupil
20 of the apparatus, may be placed at the effective centre of curvature of the focussing means.

The invention will now be described, by way of example only, with reference to the accompanying drawings, in which:

25

Figure 1 is a millimetre wave imaging apparatus of the prior art;

Figure 2 is a schematic diagram of a first embodiment of an imaging apparatus according to the present invention;

30

Figure 3 is a schematic diagram of a focussing arrangement of the imaging apparatus of Figure 2;

5 Figure 4 is a representation of an elliptical scan path produced by the imaging apparatus of Figure 2;

Figure 4a is a representation of elliptical scan paths incident upon three linear arrays;

10 Figure 5 is a schematic diagram of a second embodiment of an imaging apparatus according to the present invention; and

Figure 6 is a circular scan path produced by the imaging apparatus of Figure 5.

15

Referring now to Figures 2 to 4a, a millimetre wave imaging apparatus 200 comprises a scanning mechanism 202, a focussing device 210 and a receiver array 212.

20 The scanning mechanism 202 comprises first and second disc shaped wedge prisms 204, 205, typically a Risley prism, that are connected to respective drive mechanisms 206, 208. For small beam deviations, typically a few degrees, a low loss wedge shaped piece of refractive index, such as polythene, can be used while for large beam deviations,
25 typically ten degrees or more, a wedge of "Lettington reflector lens" can be used. A "Lettington reflector lens" comprises two linearly polarising grids, having a polarisation difference of 45° therebetween, that are separated by a sheet of Faraday rotator that rotates the polarisation by 45° .

30

The prisms 204, 205 are connected to respective drive mechanisms 206, 208 such that they counter-rotate (in opposing directions) about their respective centres, typically at more than 25 Hz. The drive mechanisms 206, 208 are arranged to create an elliptical scan pattern. Such an elliptical scan pattern is sufficient to scan a number of linear arrays in the focal plane.

The focussing device 210 (essentially a reflector lens, also known as a Lettington lens) comprises a first grid 214 typically of metallic wires, typically either horizontally or vertically aligned, a polarisation altering element 216, typically a meanderline structure, Ferrite or a Faraday plate, usually arranged to rotate the polarisation of incident radiation by 45° , and a second grid 218 usually of metallic wires, normally inclined at 45° , to the first grid 214. The scanning mechanism 202 is located optically at the radius of curvature of the first grid 214, by reflection in the grid 218. As the scanner defines the entrance pupil of the imager this arrangement reduces optical aberrations of coma and astigmatism. Physically this means the scanning mechanism 202 is next to the curved grid 214. As the receiver array 212 needs to be in the focal plane of the focussing device 210, these devices are physically adjacent to each other. This means the scanning mechanism 202, the focussing device 210 and the receiver array 212 are physically next to each other, which offers a very compact arrangement.

The receiver array 212 is made up of a plurality of radiometer receiver arrays 220a-e (shown extending into the plane of the paper), each array typically comprising input feedhorns and detector elements. The receiver arrays 220a-e are typically linear or curvilinear and are composed of a plurality of receiver elements.

In use, radiation 222a incident upon the first rotating prism 204 is refracted by an amount that is dependent upon the thickness of the prism 204 at the point at which the radiation 222a impinges upon the prism. As the prism 204 is of variable thickness and is rotating, radiation impinging
5 upon the prism 204 at the same point in space will be subject to a degree of refraction that varies with time. This effect is also achievable by the use of a rotating prism of constant thickness but varying refractive index.

Radiation 222b passes between the first prism 204 and the second prism
10 205 where it is refracted for a second time, again with a time varying magnitude due to the rotation of the second wedge prism 205.

Radiation 222c impinges upon the first grid 214 of the lens 210 where it is selectively linearly polarised orthogonal to the orientation of the grid
15 214 to produce radiation 222c'. The polarisation altering element 216 rotates the polarisation of the radiation 222c, typically by 45° , to produce radiation 222d. This radiation 222d is reflected by the second grid 218 such that radiation 222e passes back through the polarisation altering element 216 and has its polarisation rotated further, usually by 45° .
20 Radiation 222f now has a planar polarisation that is parallel to the wires of the first grid 214. This radiation is therefore reflected therefrom back through the polarisation altering element 214 to produce radiation 222g that is polarised perpendicularly the wires of the second grid 218 and can therefore pass through the second grid 218 and is focussed onto the
25 receiver arrays 220a-e.

The result of such an optical arrangement is that a field of view 250 is divided into a number of overlapping elliptical scan paths 252a-e. Scan path 252a is the part of the field of view that is projected, portion by
30 portion, onto a single array element of the array 212 as the prisms 204, 205 rotate.

The minor diameter of the elliptical scan paths 252a-e are typically such that they correspond to half the spacing of linear elements 253a-h of an array 254a-c. This allows adjacent elements 253a-h of a linear array 254a-c to measure the same region of space, thus allowing relative calibration, which improves image quality. Such a sampling also allows Nyquist sampling in the direction of the array 254a-c. This is because to achieve Nyquist sampling in a perfect array sampling is needed between the elements. The only way this can be achieved is by mechanically scanning to sample between the feed locations, the elements. The major diameter of the scan paths 252a-e correspond to the distance between the arrays 254a-c. In this way all regions of space in the field of view are scanned. Furthermore, with the major elliptical diameter corresponding to the array separation, array elements 253a-h of one linear array 254a measure the same region of the image as the adjacent array 254b once per revolution. This overlap can be used for relative calibration, which improves image quality.

The major diameter of the scan paths 252a-e are typically such that regions between the linear arrays 220a-e can be sampled and the wedge angle of the prisms 204, 205 is such that there is overlap between the arrays 220a-e. The relative speed of rotation of the prisms 204, 205 within the imaging apparatus 200 that allows the formation of elliptical scan patterns. This allows Nyquist sampling in the direction perpendicular to the receiver arrays 220a-e and also allows relative calibration of array elements between the receiver arrays 220a-e.

Referring now to Figures 5 and 6, an imaging apparatus 500 comprises a wedge prism 502, a drive mechanism 504 for rotating the prism 502, a reflector lens 506 and a receiver array 508.

The reflector lens 506 comprises a first grid 510, typically of wires, a polarisation altering element 512, typically a meanderline, Ferrite or Faraday plate, usually arranged to rotate the polarisation of incident radiation by 45° , and a second grid 514. The reflector lens 506 operates
5 substantially as hereinbefore described with reference to the reflector lens 110 of Figure 1.

Radiation 516 incident upon the prism 502 undergoes a time varying magnitude of refraction such that upon passing through the reflector lens
10 506 a circular scan path 550 is traced in a focal plane of the imaging apparatus 500.

Typical receiver array 508 configurations for such an optical arrangement include linear and two-dimensional sparse arrays.

CLAIMS

1. A millimetre wave imaging apparatus comprising scanning means,
5 focussing means and a plurality of receiver elements, the focussing means being physically interposed between the scanning means and the receiver elements, the scanning means being arranged to scan radiation from a field of view onto said focussing means such that focussed radiation from a region of the field of view is incident upon at least one of the plurality
10 of receiver elements.
2. Apparatus according to Claim 1 wherein the scanning means is a prism.
- 15 3. Apparatus according to Claim 2 wherein the prism is a wedge prism.
4. Apparatus according to Claim 2 wherein the prism is of uniform thickness and varying refractive index across a cross-section thereof.
20
5. Apparatus according to any one of Claims 2 to 4 wherein the prism is arranged to rotate.
6. Apparatus according to Claim 5 wherein the prism is arranged to
25 produce a circular scan path in the focal plane.
7. Apparatus according to any preceding claim wherein the scanning means are two prisms.
- 30 8. An apparatus according to Claim 7 wherein each of the prisms is arranged to rotate.

9. An apparatus according to Claim 8 wherein the prisms are arranged to rotate in opposite directions to each other.

10. An apparatus according to any one of Claims 7 to 9 wherein the
5 prisms the arranged to produce an elliptical scan path in the focal plane.

11. An apparatus according to Claim 10 wherein the elliptical scan path has a minor diameter that approximately corresponds to a spacing between adjacent receiver element of an array.

10

12. An apparatus according to any one of Claims 7 to 11 wherein the prisms is arranged to rotate at a rate of at least 25 revolutions per second.

13. An apparatus according to any preceding claim wherein the
15 plurality of receiver elements are arranged in a linear array, a curvilinear array or a sparse two dimensional array.

14. An apparatus according to any preceding claim wherein the focussing means is a reflector lens.

20

15. An apparatus according to Claim 14 wherein the reflector lens comprises a first polarising element.

16. An apparatus according to either of Claims 14 or 15 wherein the
25 reflector lens comprises a second polarising element arranged to reflect radiation transmitted by the first polarising element.

17. An apparatus according to any one of Claims 14 to 16 wherein the reflector lens comprises a polarisation altering element.

30

18. Apparatus according to any preceding claim wherein the scanning means, which is arranged to define an entrance pupil of the apparatus, is placed at the effective centre of curvature of the focussing means.

ABSTRACT

IMAGING APPARATUS

5 A millimetre wave imaging apparatus (200) comprises a scanning mechanism 202, a reflector lens (210) and a receiver array (212). The scanning mechanism (202) comprises two wedge prisms (204, 205) which scan radiation incident upon them across the receiver array (212) in an elliptical pattern.

10

This optical configuration is such that the pupil plane, defined by the scanning mechanism 202, is located optically at the centre of curvature of the focussing surface 214, which reduces coma and astigmatism optical aberrations.

15

To be accompanied when published by Figure 2 of the drawings.
